Pharmacy System

Problem Definition:

We as a group have been hired to put together a tracking application for pharmacies to help provide better information about their medication and customers. Many pharmacies do not have an efficient management system and still use bookkeeping methods which take up space because of storing the papers, it is also somewhat challenging to search for a specific document. We feel that our system will allow these pharmacies to operate more efficiently and have their information recorded more accurately.

Problem Solution:

Our Solution would be to create a pharmacy system to track Medication that goes in and out of the pharmacy. The system should manage employees. Employees will have a **name**, **gender**, **job title** and **contact number**. The job title's comprise doctor, secretary, cashier, and customer.

The **customer** goes to the doctor's office. The **secretary** tells the patient to be seated and wait for their turn. The **doctor** sees the patient and tells the patient they need a specific type of medication to help them get over their sickness. The patient gets a **prescription** from the doctor and the doctor tells them to visit the local **pharmacy**. The secretary updates the patient's **consultation record** once they are done. The patient visits the pharmacy where they hand the cashier the prescription. The **cashier** gets the medication, and the customer pays for it. The patient then receives a **receipt** of purchase. Having this information stored in a database allows the system to easily keep track of how much medication is being sent out, and how much medication the pharmacy needs to order from the **supplier**. This is to make sure that the pharmacy's **inventory** numbers are up to date and ensure that the pharmacy always has stock.

Actors:

pharmacy	prescription
medication	consultation record
employees	contact type
Job title	receipt
customer	inventory
supplier	employee contact
